ABSTRACT
As the Internet of Things continues to take hold in the commercial world, the teams designing these new technologies are constantly evolving and turning their hand to uncharted territory. This is especially key within the field of secondary service design as businesses attempt to utilize and find value in the sensor data being produced by connected products. This paper discusses the ways in which a commercial design team use smart thermostat data to prototype an advice-giving chatbot. The team collaborate to produce a chat sequence through careful ordering of data & reasoning about customer reactions. The paper contributes important insights into design methods being used in practice within the under researched areas of chatbot prototyping and secondary service design.

KEYWORDS
IoT; energy; design; data work; chatbot; work practice; prototyping.

INTRODUCTION
The hyped ‘vision’ for the Internet of Things (IoT) sees large quantities of sensor data being made available from a plethora of ubiquitous connected devices. This data lends itself to the production of secondary services [4], also referred to as value-added services [7], which provide auxiliary functionality to devices and services connected to the IoT. The practical reality of designing these services, presents some significant challenges for design teams, as they attempt to make sense of human, social activity from heterogeneous data sets. This paper looks at how a commercial Digital Research and Development (R&D) team use smart thermostat (ST) data as a design resource to prototype an advice-giving chatbot.
Previous studies in this area have looked at how smart home data can be used, interpreted and accounted for by household members [8] and also how design can support the use of smart home data to provide advice and insights to householders [2]. These studies highlight some of the challenges that design teams face when reusing smart home data to design secondary services. This raises the question of how commercial design teams are adapting to these new challenges and incorporating IoT data into their design work. Chatbot interaction design is also an emerging area of HCI research [3] where there is a distinct lack of design methods and frameworks that can be utilized by practitioners. There are a number of papers that discuss elements of chatbot design [1, 5, 6], however, the main focus of these is on the system elements of the design in terms of the natural language processing (NLP) and knowledge retrieval techniques. There is very little discussion about the design of the responder element [1] and no mention of prototyping methods or processes to support commercial design teams. Insight is needed into the design work involved in prototyping chat sequences as a practical accomplishment.

This paper unpacks an R&D team design meeting, within a large energy company, as they approach the challenge of adding value to smart home data through a prototype chatbot.

THE STUDY

The case study reported in this paper forms part of wider work looking at the challenges of design practitioners working with the IoT. The data gathering aspects consisted of ethnographic fieldwork. As an experienced design practitioner, the first author of this paper was embedded as a participant observer throughout the work. The approach to the research data consisted of 3 phases; participation, familiarization with the research data and evaluation of the team’s approach to adding value to data.

To avoid any confusion the following terms have been used: ‘Chat’ refers to conversational sequences being designed within the chatbot. ‘Data’ refers to the resources the team are working with. ‘Research data’ refers to data observed and recorded as part of the research study.

The design meeting discussed in this paper was recorded as part of a larger corpus of data collected during a 2 week sprint. The sprint involved the team focusing on the creation of a prototype to test the technical feasibility of using customer and IoT data to provide advice to customers through a chatbot system.

It is important to note that the meeting occurred 5 days into the sprint so the team had already familiarized themselves with the systems that they were using and the available data.

There were 3 members of the team invited to the meeting by the Project Manager (PM), which comprised of Liz, Hugo and Neil. Liz had been working on the front end of the chatbot, creating the wording and structure for the chat. Hugo and Neil had been focusing on the data streams and how they could utilize them to provide information and advice. The PM took the lead throughout the
Designing with Data: A Case Study

Transcript 2: The team assess the options they would like to offer the user within the chat sequence. Based on this discussion the team restrict the users options at this step and decide to deliver the data in a step by step manner

1: PM: So we can’t offer them the choice
2: of looking at how long their heating
3: is on, the temperature they’ve set.
4: H: So you, you can definitely do that, but
5: the thing is, average set point and
6: average outdoor temperature are two
7: entities that are used to uh.
8: PM: you’re saying that this is a product
9: of the other two things?
10: H: yes
11: L: ((nods))
12: H: I mean, the cause is how long your
13: heating is on. I mean, the consequence
14: of the average set point and the average
15: outdoor temperature is how long your
16: heating is on.
17: N: and then you answer to the question
18: why. Why is the data. What is the data.
19: PM: ok, so we have to do it differently.
20: ((rubs out button on whiteboard)) so the
21: only thing we can offer then. Well the
22: first thing we have to offer them, is
23: information about how long their boiler
24: has been running.

The meeting itself focused on the designing of one chat sequence, or ‘journey’, as the team referred to it. The work was purely focused on the conversational elements of the chatbot’s user interface (UI). The technical aspects of the chatbot infrastructure had previously been decided upon and were not part of the design work in this meeting. The prototype was an initial iteration designed to get feedback on the UI elements of the project. As such, the design task was to create a chat sequence in a fairly static way. Later iterations were planned to include the NLP & machine learning elements.

FINDINGS

One of the key challenges faced by the team was how to make data meaningful so that it added value for the customer. There were 5 data streams that the team had the potential to use to provide insight to users within the chat sequence. The ST provided boiler on-time (BO) and thermostat set point (SP). Based on the design brief and the initial fixed steps of the journey, it was implied that these core data streams would be included. These were key resources from which the team could draw inferences about activity in the home. Another data stream that was fairly central to this design task was weather data, or more specifically outdoor temperature (OT). This was considered important by the team and its inclusion was discussed on a number of occasions.

The final 2 potential data streams were Customer and Energy Performance Certificate (EPC) data. These were not included in this journey as they were referred to as having their ‘own journeys’. Relationships between journeys was mentioned as something to be reviewed in a future project phase.

Assessing relevance

The team assigned a sequential order to the data in relation to the design brief. This was not mapped out in a formal manner but can be seen throughout the discussions, with an example of this is shown in transcript 1 where BO was introduced as having a large impact on a customers bill (lines 1-3). The assumption here was that if the heating is on for less time then the customer will save money, thus making it directly relevant to the initiating question, ‘how can I save money?’. In transcript 2 this sequential order is further cemented. The PM initially (lines 1-3) asks for justification from Hugo about his justification for blocking a previous suggestion of giving the customer the option to choose which data they would like to look at. Hugo responds to this (lines 4-7) by clarifying that it is possible from a practical perspective. He then presents a justification which highlights why BO is the most relevant to the initiation question (lines 12-16). The PM accepts this justification (line 19) and adopts the view that BO has to be presented first (line 22).

This relationship mapping that the team assigned between the data and the initiation question ultimately provided the structure for the chat sequence. This is in contrast to how interesting the
Transcript 3: The team are discussing what content to include in the next step of the sequence. The focus is brought back to how the information can be used by the user to meet their goal of saving money. A scenario is used to highlight the users motivation based on the initiation question in the design brief.

1: PM: So boiler on-time is interesting but the reasons for the boiler being on are more interesting do you think? Do you agree?
2: H: Yeah yeah yeah
3: PM: Because that’s something you can do something with or not. Even knowing that my boiler was on for 172 hours doesn’t really help me. It just states the fact.
4: H: But you have to state it anyway
5: PM: Of course, no I agree that, but knowing now. The bit I wanna know, ok fine, but what do I do? that’s why I’m here, I wanna save money so what do I do to reduce this? ((taps the BO step on the whiteboard))

Adopting the customer perspective

One of the key elements of this design task, as specified in the design brief, was that the chat needed to be understandable and customer friendly. By defining the question that initiates the journey the team provide a reasonable sense of the goals and motivations of their user. Designing the prototype in this static manner enables the team to draw on scenarios & predict reactions related to the customers’ goals. This direct approach can be seen throughout the meeting to further assess the relevance, meaning and value of the chat steps in the journey.

Scenarios are used to reason about how the customer will be utilizing the information presented to them. They can be presented by any member to support an argument. Transcript 4 demonstrates how the PM draws on a scenario to make his doubts about the relevance of the OT data stream accountable to the team. He introduces a scenario by first stating his belief that weather information is only relevant in some circumstances (lines 1-3). A usage scenario is then delivered in the first person perspective giving an example of when the information would be meaningless to a user (lines 6-14). The inclusion of the initiation question (line 8) is used to highlight the customer’s goal as he moves between the design brief and the customer perspective to frame his argument. As a result of this discussion the team decide to drop the OT data from this journey.

Transcript 3 shows an example of another scenario being used to demonstrate how the data meets the assumed goals and expectations of the user (lines 12-15). In this example the scenario is intertwined with other conversational elements. The PM switches between conversation about the data and delivering a scenario. The scenario is made accountable to the other members by the use of the first person perspective, allowing the PM successfully switch his assumed role from designer to user. In this case the purpose of the scenario is not only tied to a specific step in the chat journey but is also used to refocus the team on the design brief and the assumed customer goal, in a more general way, relating to the design task of the journey as a whole.

In addition to the use of scenarios the team also rely on predictions of customer reactions. These are much shorter than the scenarios and as such, are drawn on more regularly throughout the task. Their purpose is similar, they are used to justify or back up a decision or argument in relation to members believe the data is. There are many occasions where data is labelled as ‘interesting’ or ‘more interesting’ than another data stream. Transcript 3 shows an argument that states while BO is interesting, SP & OT are more interesting as they can explain BO (lines 1-3). The terms interesting and meaningful are used to refer to data outputs that are insightful or actionable for the customer. This is a type of relevance in itself that links to customer goals and motivations but one that supports the sequential order of the chat journey rather than driving it. By assessing the relevance in these ways the members are able to map the data from the initiation question through to actionable insights in a step by step manner.
Designing with Data: A Case Study

Transcript 4: The team are deciding whether or not to include weather data in the chatbot. An example scenario is offered to reason about how relevant and meaningful it would be to a user. As a result of this discussion the team decide not to include the data stream.

1. PM: so there are some quite specific
2. conditions under which weather
3. information is relevant to that person’s
4. visit.
5. H: mmhmm
6. PM: because if I’ve just come on and I go
7. through Liz’s welcome thing and I see
8. how to save money as an option, and I
9. click on it, and it’s August, knowing
10. what the average weather or what the
11. average temperature was in the last 30
12. days against the rest of the UK, or last
13. 30 days against the previous 30 days
14. it’s kind of meaningless isn’t it.

whether or not it adds value or meaning to the customer. These predicted reactions can be either positive or negative. Transcript 1 shows an example of a positive predicted reaction being presented to support an argument for adding a context step before introducing the BO data (lines 4-5). The justification for the additional step is to set the frame of mind of the visiting customer, by making the meaning of the data presented in the following step explicit. In contrast, transcript 5, gives an example of a negative predicted reaction as Hugo suggests presenting the BO data in hours over a 30 day period may cause the customer to freak out (line 10).

DISCUSSION

The findings demonstrate how the team collaboratively work through the task of creating a prototype chat sequence that adds value to ST data streams. The constraints placed on the task, through the specific design brief and decision to keep the prototype fairly static, frame the task in a way that maintained focus on adding value to the data. The team can be seen to create a sequential order to the data that is used to drive the step by step elements of the design. This approach sees the systematic linking of the data to the design brief as they draw on their knowledge of the data streams. The method of creating a step by step mapping of the chat sequence provides some interesting insights into chatbot design work. The sequence mapping seen in this case was performed before any NLP & ML elements were included, thus giving potential for user testing to be performed on the user UI elements in a somewhat controlled manner.

The focus on the customer within the design brief appeared to encourage the team to reason about how the customers would be using and reacting to the information that was being presented to them. This ties into some of the challenges discussed by [2, 8]. Scenarios and predicted reactions were drawn on to justify design ideas and support decisions. At such an early stage of the project, before any user feedback had been received by the team, they used their knowledge about their customers and personal experience to draw on. This technique was central to the design task in respect to how the team were progressing and reviewing their progress in relation to adding value to the data.

CONCLUSIONS AND FUTURE WORK

Design using sensor data to add value through secondary services is a complex task. This study demonstrates how the team find sequential order in the data to drive the structure of the design forward. Value is added through a process of reasoning about how the users will use and react to the information presented to them. Insights are also provided in relation to the work of prototyping of a chatbot UI designed to facilitate future user testing opportunities.

Future work will look at the wider corpus of data across the whole 2 week sprint, along with additional studies of practice in this area.
This paper opens up a view into complexities involved in design with IoT data and highlights current methods of commercial chatbot design work. More work is needed to enable HCI to provide support to practitioners in the under researched areas of Chatbot prototyping and secondary service design.
